

Introduction to Routing Techniques and Theory (CCNA 2)

Lab Portfolio
Spring 2006

Rich Simms
May 12, 2006
CIS 82
Cabrillo College

Table of Contents

Lab 1: Introduction to using the router

Lab 2: Router configuration

Lab 3: Password Recovery and TFTP

Lab 4: Static Routes

Lab 5: RIP

Lab 6: IGRP

Lab 7: ACL

Case Study

Example Commands

Worksheets (additional lab work)

CIS 82 - LAB 1: Introduction To Using The Router

Rich Simms

February 21, 2006

Teammates:

- Louis Arbanas
- Eric Jett
- Alf Popp

1 – Scenario

We used one Cisco Model 1720 Router attached to one Windows XP PC console. On the console PC we used the TeraTerm terminal emulation software. The objective of this lab was to learn how to cable a console to the router and explore some basic IOS commands.

2 – Diagram

Lab 1 scenario

Cisco models 1720 (upper) and 1721 (lower)

“Cape Town” pod

Flat rollover cable

3 – Running Configurations

```

Router#show running-config
Building configuration...

Current configuration : 513 bytes
!
version 12.1
no service single-slot-reload-enable
service timestamps debug uptime
service timestamps log uptime
no service password-encryption
!
hostname Router
!!
memory-size iomem 15
ip subnet-zero
!
!!
interface Serial0
no ip address
shutdown
!
interface Serial1
no ip address
shutdown
!
interface BRID
no ip address
shutdown
!
interface FastEthernet0
no ip address
shutdown
speed auto
!
ip classless
no ip http server
!
!
line con 0
line aux 0
line vty 0 4
!
no scheduler allocate
end

Router#

```

4 – Troubleshooting/Reflections

This lab went smoothly without any real problems. It took a little while to become familiar with the pods, the router backplanes, the various cables and how to power up everything. We started with HyperTerminal then switched to TeraTerm. We had to increase the number of lines TeraTerm would save so we could record everything. We copy and pasted console output from TeraTerm into a Word document and transferred that to a USB memory stick. We created an online collaboration website and data repository using Yahoo Groups to keep our lab data.

5 – Questions from the lab

Router Interface/Port	Cable Type	Connector	Device And Port To Which The Cable Is Connected
Console	Rollover	RJ-45	PC COM port 1 (with DB-9 connector)

Serial1	Serial (v.35)	Smart Serial Connector	Another router or WAN device
Serial0	Serial (v.35)	Smart Serial Connector	Another router or WAN device
Aux	Rollover	RJ-45	Modem
10/100 Ethernet	Straight	RJ-45	Switch
ISDN BRI U		RJ-45	ISDN device

Regarding Show Interface

- What does this command show you? (Shows detailed information and status for each router interface)
- Lots of information is shown, some of which we will discuss this semester. Is there any information you recognize? (Port names, MTUs, Ethernet parameters).
- How many interfaces does your router have and what are their names? (BRI0, BRI0:1, BRI0:2, FastEthernet0, Serial0, Serial1)
- How would you show a specific interface? (show interface serial 0)

Regarding show ip interface brief

- What kind of information does this command give you? (concise summary of interfaces)
- What is the state of the interfaces? (all down)
- Do they have IP addresses configured yet? (no, all unassigned)
- No is correct, but why not? That's right you have not configured them yet.

Match the interfaces displayed in the previous commands with the physical interfaces on the router.

BRI0, BRI0:1, BRI0:2 all go with ISDN BRI port
 Serial0 goes with Serial0 port
 Serial1 goes with Serial1 port
 FastEthernet goes with 10/100 Ethernet port

Question: What do each of the following features do? (Short-term CCNA v2 exam knowledge.)

- CTRL-B = go "Back One Character". (can also use LEFT Arrow key)
- CTRL-F = go "Forward One Character". (can also use RIGHT Arrow key)
- CTRL-A = goes to the "Beginning" of the Line.
- CTRL-E = goes to the "End" of the Line.
- ESCAPE and B = go "Backward to the Beginning of the Next Word".

- ESCAPE and F = go "Forward to the Beginning of the Next Word".

6 – Example Commands

Erasing NVRAM

```
Router>enable
Router#erase startup-config
Erasing the nvram filesystem will remove all files! Continue? [confirm]
[OK]
Erase of nvram: complete
Router#
```

The penalty for making a typo

```
Router#confirm
Translating "confirm"...domain server (255.255.255.255)

Translating "confirm"...domain server (255.255.255.255)
(255.255.255.255)% Unknown command or computer name, or unable to find computer
address
Router#
```

Power router off and on

```

STEP 4 - Basic Commands

Help (non-privileged level)

```
Router>?
```

```
Exec commands:
```

access-enable	Create a temporary Access-List entry
access-profile	Apply user-profile to interface
clear	Reset functions
connect	Open a terminal connection
disable	Turn off privileged commands
disconnect	Disconnect an existing network connection
enable	Turn on privileged commands
exit	Exit from the EXEC
help	Description of the interactive help system
lock	Lock the terminal
login	Log in as a particular user
logout	Exit from the EXEC
mrinfo	Request neighbor and version information from a multicast router
mstat	Show statistics after multiple multicast traceroutes
mtrace	Trace reverse multicast path from destination to source
name-connection	Name an existing network connection
pad	Open a X.29 PAD connection

```

ping          Send echo messages
ppp          Start IETF Point-to-Point Protocol (PPP)
resume       Resume an active network connection
rlogin       Open an rlogin connection
show         Show running system information
slip         Start Serial-line IP (SLIP)
systat       Display information about terminal lines
telnet       Open a telnet connection
terminal     Set terminal line parameters
traceroute   Trace route to destination
tunnel       Open a tunnel connection
where        List active connections
x28          Become an X.28 PAD
x3           Set X.3 parameters on PAD

```

Router>

Help (privileged level)

Router>enable

Router#?

Exec commands:

```

access-enable Create a temporary Access-List entry
access-profile Apply user-profile to interface
access-template Create a temporary Access-List entry
archive        manage archive files
bfe            For manual emergency modes setting
cd             Change current directory
clear          Reset functions
clock         Manage the system clock
configure      Enter configuration mode
connect        Open a terminal connection
copy           Copy from one file to another
debug          Debugging functions (see also 'undebug')
delete         Delete a file
dir            List files on a filesystem
disable        Turn off privileged commands
disconnect     Disconnect an existing network connection
elog           Event-logging control commands
enable         Turn on privileged commands
erase          Erase a filesystem
exit           Exit from the EXEC
help           Description of the interactive help system
isdn           Make/disconnect an isdn data call on a BRI interface
lock           Lock the terminal
login          Log in as a particular user
logout         Exit from the EXEC
more           Display the contents of a file
mrinfo         Request neighbor and version information from a multicast
               router
mrm            IP Multicast Routing Monitor Test
mstat          Show statistics after multiple multicast traceroutes
mtrace         Trace reverse multicast path from destination to source
name-connection Name an existing network connection
no             Disable debugging functions
pad            Open a X.29 PAD connection
ping           Send echo messages
ppp            Start IETF Point-to-Point Protocol (PPP)
pwd            Display current working directory
reload         Halt and perform a cold restart
resume         Resume an active network connection
rlogin         Open an rlogin connection
rsh            Execute a remote command
send           Send a message to other tty lines
setup          Run the SETUP command facility
show           Show running system information
slip           Start Serial-line IP (SLIP)
start-chat     Start a chat-script on a line
systat         Display information about terminal lines
telnet         Open a telnet connection

```

terminal	Set terminal line parameters
test	Test subsystems, memory, and interfaces
traceroute	Trace route to destination
tunnel	Open a tunnel connection
undebug	Disable debugging functions (see also 'debug')
verify	Verify a file
where	List active connections
write	Write running configuration to memory, network, or terminal
x28	Become an X.28 PAD
x3	Set X.3 parameters on PAD

Help system

```
Router>help
```

Help may be requested at any point in a command by entering a question mark '?'. If nothing matches, the help list will be empty and you must backup until entering a '?' shows the available options.

Two styles of help are provided:

1. Full help is available when you are ready to enter a command argument (e.g. 'show ?') and describes each possible argument.
2. Partial help is provided when an abbreviated argument is entered and you want to know what arguments match the input (e.g. 'show pr?').

CIS 82 LAB 2: Router Configuration

Rich Simms

February 28, 2006

Teammates:

- Louis Arbanas
- Eric Jett
- Alf Popp

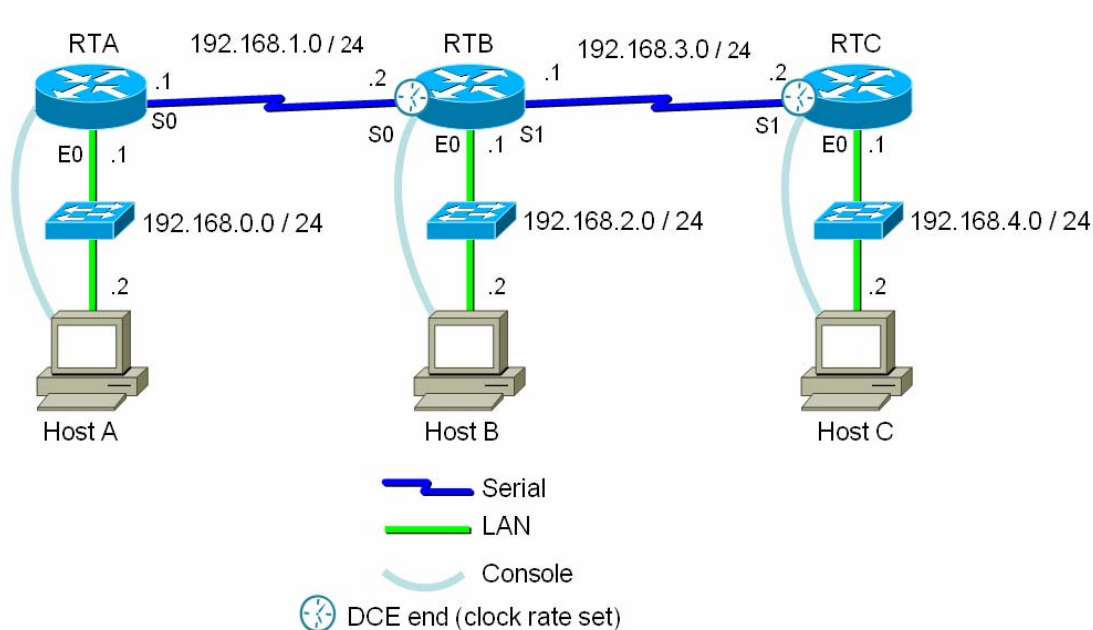

1 – Scenario

For this lab we used three Cisco routers, one switch and three PC's acting as both hosts and consoles. The routers were connected using the serial interfaces and the hosts were attached to the Ethernet interfaces. The switch was used between the hosts and the routers which allowed us to use all straight LAN cables.

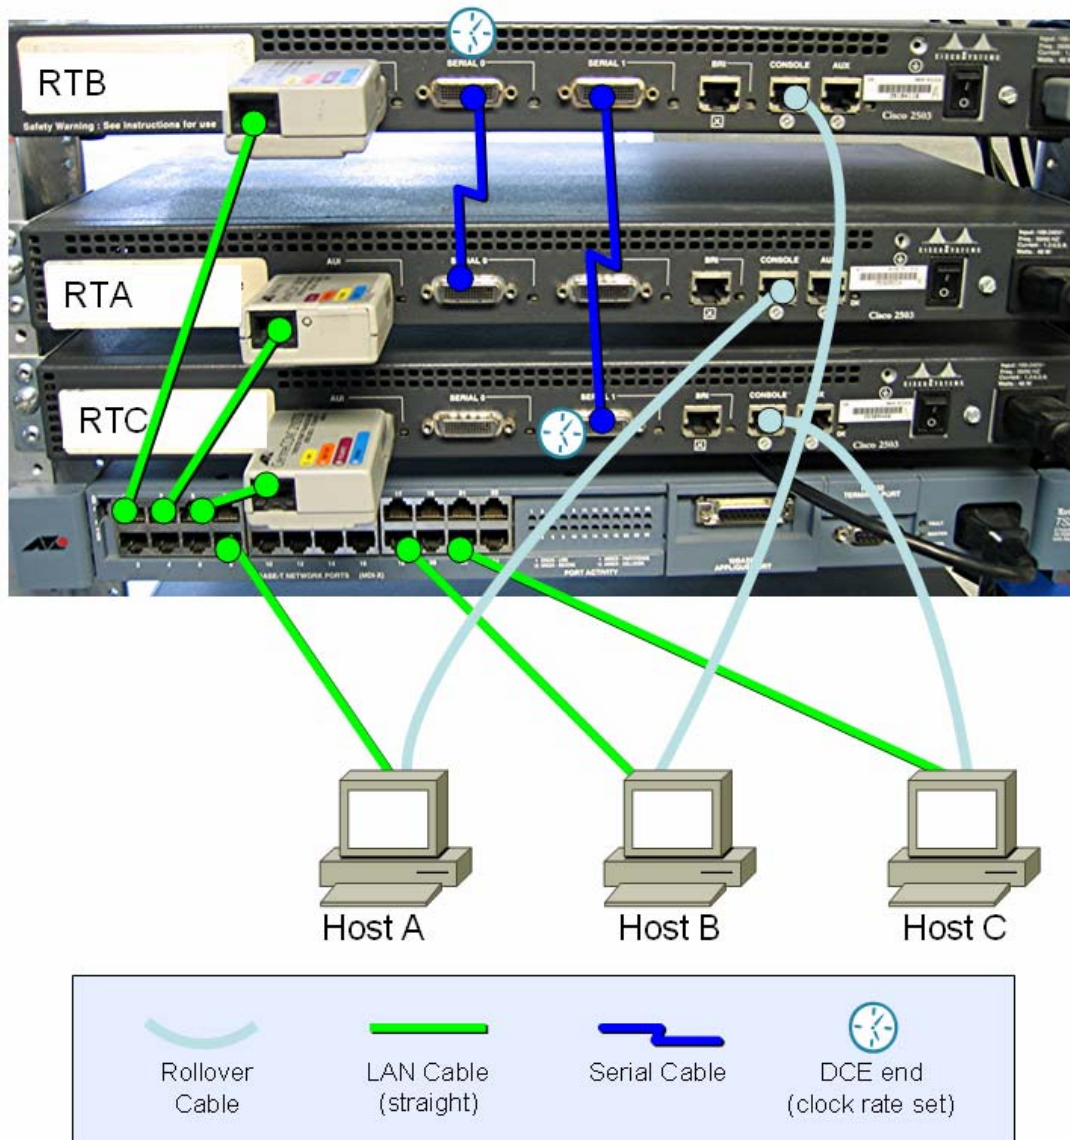

The objective of this lab was to learn how to configure interfaces, use telnet, set passwords & banners, explore CDP and debug capabilities.

2 – Diagram

Logical view:

Physical view:

3 – Running Configurations

---	--	--

4 – Troubleshooting /Reflections

Probably the most trouble with this lab was getting the cabling correct and understanding which end of the serial cables were DCE or DTE. Cabling required a slow, systematic and methodical

approach. The `ping` command was absolutely invaluable for making sure each connection worked. The `show ip int brief` was very helpful to make sure the interfaces were up and configured correctly.

5 – Questions from the lab

Regarding

Regarding clock rate command:

- Do you need to include this command on this serial interface? *It is always needed for the DCE interface.*

Regarding interface status:

- What might cause your Ethernet interface to be down? *Unconnected cable, forgetting the no shut command.*
- What might cause your Serial interface to be down? *Unconnected, faulty or incorrect cabling, forgetting the no shut command, no clock rate set on the DCE end.*
- What might cause your Serial or Ethernet interface to be administratively down? *Forgetting the no shut command.*

Regarding Show interface:

- Do you see your interface description? *yes*
- Do you see the ip address information? *yes*
- What else do you notice? *There is a great deal of information about each interface including encapsulation, MTU, bandwidth, reliability, timers, traffic statistics etc.*

Issue an extended ping command. How did you do that?

An extended ping lets you specify both source and destination IP addresses as well as other options. To run an extended ping just type ping and then you get prompted for the rest. The extended ping command works only in privileged EXEC mode while the normal ping works both in the user and privileged EXEC modes.

Regarding Telnet:

- What is the difference between telnetting into a device and accessing it via the console port? *Telnet sessions access routers on the network from anywhere on the network. The console port requires a physical connection to the router using the special rollover cable from the serial COM port on a PC.*
- What must you have configured before telnetting into the router? *A password.*

6 – Example Commands

Ping

RTA#ping rta

Type escape sequence to abort.
 Sending 5, 100-byte ICMP Echos to 162.168.1.2, timeout is 2 seconds:

 Success rate is 0 percent (0/5)

RTA#ping rta

Type escape sequence to abort.
 Sending 5, 100-byte ICMP Echos to 192.168.1.1, timeout is 2 seconds:
 !!!!!
 Success rate is 100 percent (5/5), round-trip min/avg/max = 56/56/56 ms
 RTA#rtb

RTA#ping 192.168.0.2

Type escape sequence to abort.
 Sending 5, 100-byte ICMP Echos to 192.168.0.2, timeout is 2 seconds:
 !!!!!
 Success rate is 100 percent (5/5), round-trip min/avg/max = 1/2/4 ms

RTA#config term

Enter configuration commands, one per line. End with CNTL/Z.
 RTA(config)#ip host rta 192.168.1.2
 RTA(config)#ip host rta 192.168.1.1
 RTA(config)#exit

Interfaces

RTB#show ip int brief

CIS 82 Lab 3 – WebCT submittal

Rich Simms
March 8, 2006

The objective of Lab 3 was to learn how to do password recovery and utilize an TFTP server. This abbreviated WebCT write-up contains the following sections:

- 1) Post password recovery configuration files.
- 2) Step-by-Step instructions for doing a password recovery.
- 3) Step-by-Step instructions for backing up and restoring configuration files with TFTP.

1) Post Password Recovery Configuration Files

2) Step-by-Step Password Recovery Instructions

The passwords for a router are stored in the startup-config file in NVRAM. Recovering the password involves “breaking-in” during the router bootup process and configuring the configuration register so that the startup-config file is bypassed. This allows the router to start in an un-configured state with no password. From that point the network administrator has control again of the router and can both recover configuration information as well as reset the password

The instructions below apply to the Cisco router model 2503. For specific instructions relating to other routers models see:

<http://www.cisco.com/warp/public/474/>

Step 1 – Attach a PC console to the router

- Connect a flat rollover cable from the router’s console port to the Serial COM port on a PC that will act as the console.

- Insure TeraTerm terminal emulation software is installed on the console PC.
<http://hp.vector.co.jp/authors/VA002416/teraterm.html>
- Configure TeraTerm to connect using the serial COM 1 port with 9600 baud, no parity, 8 databits, 1 stop bit, no flow control. Other COM ports can be used as well if COM 1 is not available.

Step 2 – Record current configuration register setting

- If you still have access to the router, enter a `show version` command and record the setting of the configuration register at the end of the version information:

```
Configuration register is 0x2102
```

We will use this later to restore the routers configuration register after changing it.

Step 3 – Reboot and “break in” into the router.

- Note, if this is a production router you will need to schedule this operation accordingly and notify users the network will be down.
- Reboot - power off the router, then power it back on using the router’s power switch.
- Break in - send a break sequence within 60 seconds of powering on the router. With TeraTerm this is done by typing **Alt-b** (pressing alt and b keys at the same time)
- If you hit the **alt-b** enough times during the 60 second window you will enter ROMmon mode which looks as follows:

```
System Bootstrap, Version 5.2(8a), RELEASE SOFTWARE
Copyright (c) 1986-1995 by cisco Systems
2500 processor with 8192 Kbytes of main memory

Abort at 0x10EA82E (PC)
>
```

If you don’t get into ROMmon mode the first time, keep rebooting and entering multiple Alt-b’s till you hit the right time window.

Step 4 – In ROMmon mode, reconfigure router boot to bypass startup-config and reboot again

- Use the following commands to reset the configuration register and reboot:

```
>o/r 0x42
>i
```

- When the router comes up type `no` to the setup prompt or `ctrl-c`

```
--- System Configuration Dialog ---
```

```
Would you like to enter the initial configuration dialog?
[yes/no]: no
```

Step 5 – Perform password recovery

- Enter privileged mode

```
Router>enable
Router#
```

- Restore previous startup configuration:

```
Router#copy startup-config running-config
Destination filename [running-config]?
683 bytes copied in 4.784 secs (170 bytes/sec)
simms#
```

- Set new password:

```
simms#configure terminal
Enter configuration commands, one per line.  End with
CNTL/Z.
simms(config)#enable secret class
```

- Restore the configuration register to the value recorded in Step 2:

```
simms(config)#config-register 0x2102
simms(config)#exit
simms#
```

- Save new configuration (with reset password):

```
simms#copy running-config startup-config
```

- Verify configuration register change by issuing show version command and looking at the end of the output for the restored setting of the configuration register:

```
Configuration register is 0x42 (will be 0x2102 at next
reload)
```

- Reboot the router now and check that your new password is correct.

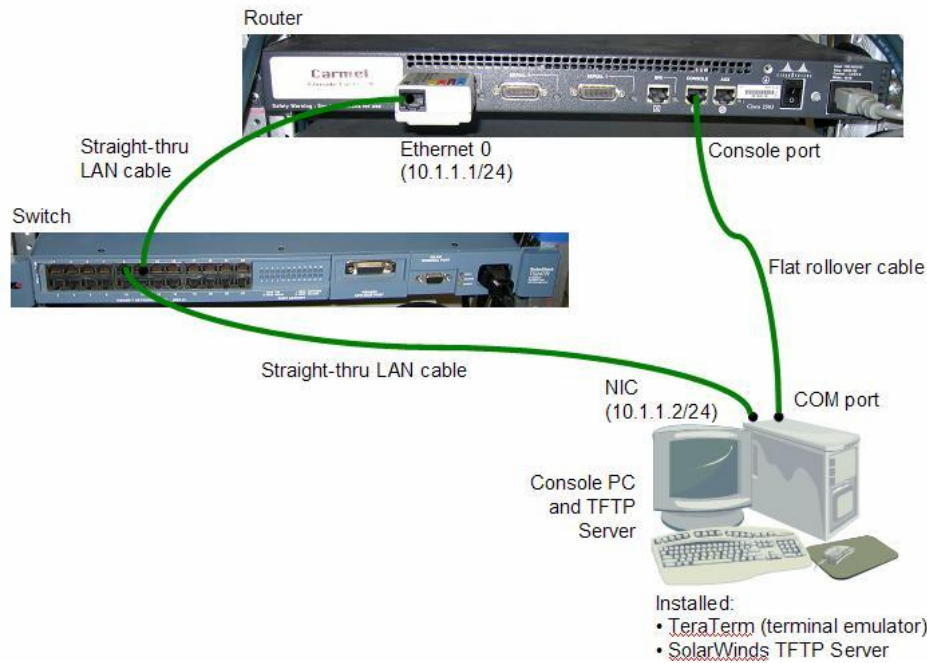

3) Step-by-Step instructions for backing up and restoring configuration files with TFTP.

IOS can copy files to and from a TFTP server. TFTP stands for trivial File Transfer Protocol and is a way to transfer files over a network. In this case we will use the SolarWinds TFTP server software on the console PC to act as the TFTP server.

The following instructions show how to backup and restore files. The example shows a particular configuration which has the TFTP server running on the console PC. This is for this example only as the TFTP server could be elsewhere on the network.

Step 1 – Connect console (and TFTP server) to the router

- Make the following connections

- Insure TeraTerm terminal emulation software is installed on the console PC.
<http://hp.vector.co.jp/authors/VA002416/teraterm.html>
- Configure TeraTerm to connect using the serial COM 1 port with 9600 baud, no parity, 8 databits, 1 stop bit, no flow control. Other COM ports can be used as well if COM 1 is not available.
- Insure SolarWinds TFTP server is installed and running.
<http://www.solarwinds.net/FreeTools.htm>

Step 2 – Configure the interfaces

- Note: for this example we will configure a 10.1.1.0/24 network for the router and TFTP server to use for file transfer. This does not have to be this specific network for TFTP transfers and other correctly configured networks can be used instead.
- On the Console PC (which is also the TFTP server) configure the LAN interface as follows:

IP 10.1.1.2

```
Subnet mask: 255.255.255.0
Default gateway: 10.1.1.1
```

- On the router, configure the Ethernet interface.

```
simms#conf t
Enter configuration commands, one per line.  End with
CNTL/Z.
simms(config)#interface ethernet 0
simms(config)#ip address 10.1.1.1 255.255.255.0
simms(config)#no shut
simms(config)#end
```

- At this time it is a good idea to check all interfaces with the ping command on the router and on the Console PC. From the router ping the PC and from the PC ping the router.
- Make sure the TFTP server is running on the Console PC.

Step 3 – Backup a configuration file to the TFTP server

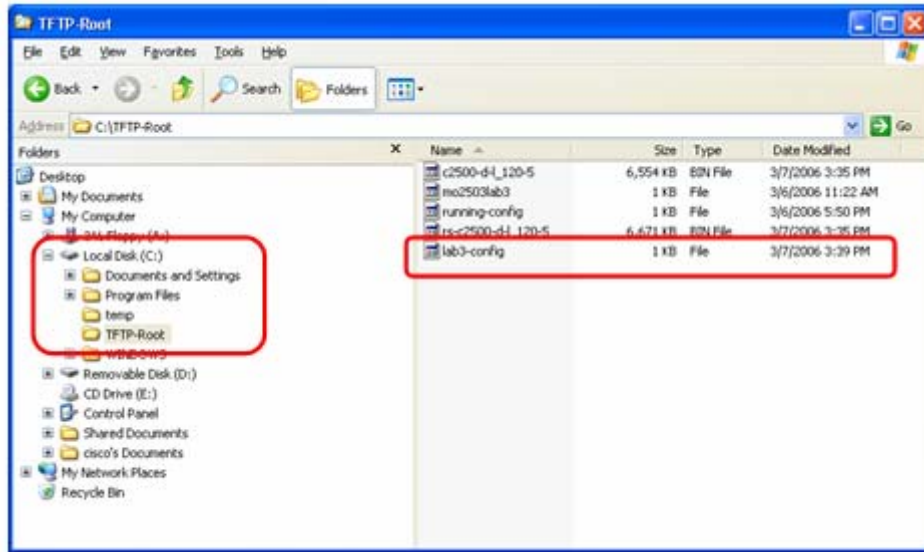

- Use the copy command to back up running-config or startup-config file. In this example we will backup the startup-config file and name it lab3-config on the TFTP server:

```
simms#
simms#copy startup-config tftp
Address or name of remote host []? 10.1.1.2
Destination filename [startup-config]? lab3-config
!!
676 bytes copied in 0.240 secs
simms#
```

- Look at SolarWinds TFTP server to verify the transfer. In this example the startup-config file on the router was copied to a file named lab3-config on the TFTP server:

- The files on the TFTP server (Console PC) are placed in the TFTP-Root directory on the C: drive by default. Use Windows Explorer to view and manage these files as needed. Best practices include adding your initials and dates to the names of these files.

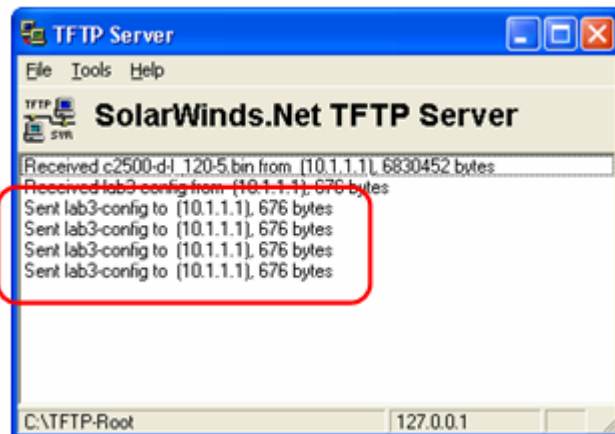

Step 4 - Restore a configuration file from the TFTP server

- Use the copy command as follows to restore the startup-config file:

```
oops#copy tftp startup-config
Address or name of remote host []? 10.1.1.2
Source filename []? lab3-config
Destination filename [startup-config]?
Accessing tftp://con/lab3-config...
Loading lab3-config from 10.1.1.2 (via Ethernet0): !
[OK - 676/1024 bytes]
```

- Look at SolarWinds TFTP server to verify it sent the file. In this example we transferred the file named lab3-config on the TFTP server back to startup-config file on the router. Note, this overwrites the file on the router.

- At this point you can view the new startup configuration file using `show startup-config` to insure it is what you wanted.
- Note the copy command could just as easily be used to backup or restore other configuration files such as `running-config`. It is also capable of backing up and restoring image files in flash.

CIS 82 LAB 3: Password Recovery and TFTP

Rich Simms

March 7, 2006

Teammates:

- Louis Arbanas
- Eric Jett
- Alf Popp

1 – Scenario

The objective of this lab was to learn how to perform password recovery, utilize a TFTP server to backup and to boot up from a TFTP server. For this lab we used one Cisco router, one switch and one PC. The PC played the role of both console and TFTP server.

2 – Diagram

!
!
line con 0
 password cisco
 login
 transport input none
line aux 0
line vty 0 4
 login
!
end
simms#

```

4 – Troubleshooting/Reflection

The most time consuming problem was trying to get the router to boot from the TFTP server. Instead of booting it would time out with the following message:

```

%SYS-6-READ_BOOTFILE_FAIL: tftp://255.255.255.255/rs-c1700-k9o3sy7-mz.122-8.T5.b
in File read failed -- Timed out.

```

Note that normal TFTP file copies worked fine and it was only the boot from TFTP that had a problem.

The Cisco web site recommended:

`%SYS-6-READ_BOOTFILE_FAIL : [chars] [chars].`

Explanation A configured boot system command has failed.

Recommended Action If this message recurs, copy the error message exactly as it appears on the console or in the system log, contact your Cisco technical support representative, and provide the representative with the gathered information.

And the Cisco site also recommended:

Q. Why do I get "Timeout" error messages?

A. Verify that the TFTP server is open on your PC. Also, make sure the file is in the root directory (from the TFTP application software menu bar, choose View > Options).

Try to eliminate extraneous networking complexities between the router and the TFTP server, such as hubs and switches, or reduce the hop count between the router and server. This may involve moving the TFTP server or setting up a new server on a network segment topologically closer to the router, or on the same LAN segment as the router.

Finally, if these actions fail to resolve the problem, try using different TFTP server software.

Trying different routers did not resolve the problem. Only when trying a different host PC did everything work properly.

Many weeks later, one of the lab techs also looked into this problem. He was able to reproduce the same boot failure. He discovered another work-around which entailed replacing the switch between the TFTP server and the router with a cross-over cable.

5 – Lab Questions

After breaking in during boot and changing the configuration register to x42 from x2102

- What does the running-config look like? **Clean (no password set)**
- What does the startup-config look like? **Has configured settings including password**
- Why is the startup-config still there? **not erased, just ignored**
- **What** happens the next time you reboot the router if you do not reset the configuration register to x2102? **will bypass startup-config again**

Regarding TFTP

- What is the difference between copying the running-config to the TFTP server or the startup-config to the TFTP server? **Running-config will have any unsaved changes**
- When does it matter which one you choose? **Should save whichever one you wish to later restore from**
- After copying the old startup-config file from the TFTP server, when will this version take effect?

Regarding booting from TFTP

- Where did the router boot from? **Booted from tftp server**
- Now, from the TFTP server's directory delete the IOS image. Reboot the router. Where do you think it will boot from now? **From Flash**
- Does it make a difference if the TFTP server is on? **Fails if tftp server is not available**
- What is the command to prevent the router from attempting to boot from the image on the TFTP server? **Just use boot system flash and delete commands to boot from tftp server**

6 – Example Commands

```

Router>
Router>enable
Router#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)#hostname simms
simms(config)#

Router#conf t
Enter configuration commands, one per line. End with CNTL/Z.
simms(config)#int e0
simms(config-if)#ip add 10.1.1.1 255.255.255.0
simms(config-if)#no shut

CIS 82 LAB 4: Static Routing

Rich Simms

March 14, 2006

Teammates:

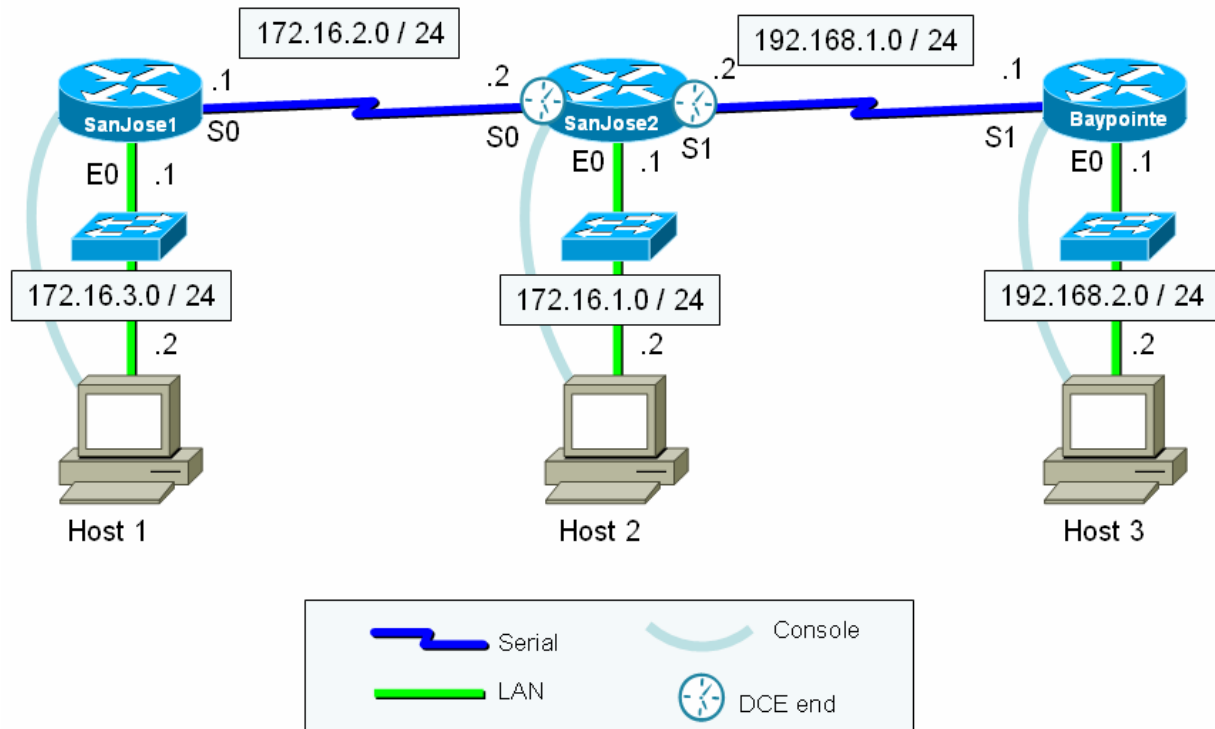

- Louis Arbanas
- Eric Jett
- Alf Popp

1 – Scenario

The objective of this lab is to learn how to configure static routing including default gateways. The scenario will include three routers configured as shown in the diagram below. Serial links are used between the routers and the Ethernet interfaces are used for LANs of single hosts.

2 – Diagram

Logical view:

3 – Running Configurations

SanJose 1	SanJose2	Baypointe

4 – Troubleshooting/Reflection

This lab went quite smoothly (unlike the last lab!). I can see how static routes would allow precise routing flow control. I also see that on large networks they would be very tedious and network changes could lead to both large and subtle routing problems.

5 – Lab Questions

What are the different classful networks?

172.16.0.0/16
192.168.2.0/24
192.168.1.0/24

Are there any subnets? If so, what are they?

172.16.1.0/24
172.16.2.0/24
172.16.3.0/24

Regarding initial static route configuration

- What routes to networks do you see?

SanJose2
Gateway of last resort is not set

172.16.0.0/24 is subnetted, 3 subnets
S 172.16.1.0 [1/0] via 172.16.2.2
C 172.16.2.0 is directly connected, Serial0

What is the administrative distance for a static route? 1

What is the administrative distance for a directly connected network? 0

How does the next-hop-ip-address help with the routing process?

It identifies the specific destination to send the packet for the next portion of the journey through the routers.

Does it give the entire route?

Not necessarily, the next-hop-ip-address only indicates the path to the next router. This could be an intermediate hop and the routing process would have to continue through each router along the path to the final destination network.

What is it actually doing regarding the routing of the packet?

The next-hop-ip-address is used if the packet's destination network is not on one of the local interfaces. The basic routing algorithm and use of the next-hop-ip-address operates as follows:

- Compute the destination network number of the destination IP address
- If the destination network matches a local interface, then the packet is forwarded out that interface.
- Otherwise if the destination network matches an entry in the routing table, then the packet is forwarded to the next-hop/interface specified in the routing table.

How does a packet get from Host 2 to Host 3?

When a framed packet arrives at a router interface, the data-link identifier in the frame destination and the address field is examined. If it contains either the identifier of the router's interface or a broadcast identifier. The router strips off the frame and passes the enclosed packet to the network layer. At the network layer, the destination address of the packet is examined. If the destination address is either the I.P. address of the router's interface or all-hosts broadcast address, the protocol field of the packet is examined and the enclosed data is sent to the appropriate process. Any other destination address calls for routing of the packet is routable, the router will do a route table lookup for the correct address

Instead of a next-hop-ip-address, what else could you have used?

The alternative to using the next-hop address would be to specify one of the router interfaces instead.

What would you need to do if you added new networks or deleted/modified existing networks?

The routing tables would have to be updated to reflect the changes in the topology

Is there any way to summarize several static routes to multiple subnets into a single static route?

You can "supernet" individual subnets together by using a mask that applies to multiple subnets. For example you could specify all three 17.16.x.x subnets with a 255.255.0.0 mask.

Regarding summary static routes

- What routes to networks do you see?

What is the administrative distance for a static route? 1

What is the administrative distance for a directly connected network? 0

How does the next-hop-ip-address help with the routing process?

It identifies the specific destination to send the packet for the next portion of the journey through the routers.

Does it give the entire route?

Not necessarily, the next-hop-ip-address only indicates the path to the next router. This could be an intermediate hop and the routing process would have to continue through each router along the path to the final destination network.

What is it actually doing regarding the routing of the packet?

The next-hop-ip-address is used if the packet's destination network is not on one of the local interfaces. The basic routing algorithm and use of the next-hop-ip-address operates as follows:

- Compute the destination network number of the destination IP address
- If the destination network matches a local interface, then the packet is forwarded out that interface.
- Otherwise if the destination network matches an entry in the routing table, then the packet is forwarded to the next-hop/interface specified in the routing table.

How does a packet get from Host 2 to Host 3?

When a framed packet arrives at a router interface, the data-link identifies in the frame destination and the address field is examined. If it contains either the identifier of the router's interface or a broadcast identifier. The router strips off the frame and passes the enclosed packet to the network layer. At the network layer, the destination address of the packet is examined. If the destination address is either the I.P. address of the router's interface or all-hosts broadcast address, the protocol field of the packet is examined and the enclosed data is sent to the appropriate process. Any other destination address calls for routing of the packet. If the packet is routable, the router will do a route table lookup for the correct address.

Instead of a next-hop-ip-address, what else could you have used?

The alternative to using the next-hop address would be to specify one of the router interfaces instead.

What would you need to do if you added new networks or deleted/modified existing networks?

The routing tables would have to be updated to reflect the changes in the topology.

Is there any way to summarize several static routes to multiple subnets into a single static route?

Yes all subnets can be summarized into their classful networks.

Do you think static routes still used even with dynamic routing (RIP, OSPF, etc.)?

Yes, It is common to use a static route where using a dynamic routing protocols would have disadvantages or where it just not needed. Static routes can be preferable for security, performance or administrative reasons. For example, stub networks are like dead-end streets with only one link to the main network.

Do you think default static routes still used even with dynamic routing (RIP, OSPF, etc.)?

Yes, default static routes are useful for connecting stub networks.

What is the disadvantage of doing this? How would a default static route be properly used in a real world network? (How would a company's network use a default route when connecting to the Internet?)

As with other summary routes, the trade off with default routes is a loss of routing detail. The stub routers have no way of knowing if a destination is unreachable. All packets are forwarded to hub router, and only then is the reachability determined. Some example real world scenarios of networks that would benefit from default static routes are branch offices and home networks. The branch offices all connect back into the larger corporate network. Home networks will have a single connection to their ISP's router to get internet access.

6 – Example Commands

```
!*****
! Create static routes
!*****

!set route using net hop address
conf t
  ip route 172.16.1.0 255.255.255.0 192.168.1.2
  no ip route 172.16.1.0 255.255.255.0 192.168.1.2

!Setup default routes
conf t
  ip route 0.0.0.0 0.0.0.0 192.168.1.2
  no ip route 0.0.0.0 0.0.0.0 192.168.1.2
  ip route 0.0.0.0 0.0.0.0 s1
  exit

!Alternate default GW that works with RIP and IGRP advertisements
conf t
  ip default-network 10.0.0.0
  exit

! to verify routes
show ip route
show run
```

Scenario 2

Scenario 2 examines RIPv1 running on subnets and between classful networks. This scenario uses three routers and three hosts as shown below. Now there are only three classful networks (172.30.0.0, 192.168.4.0 and 192.168.5.0) and some are subnetted. RIP v1 is configured on each router. This scenario is pushing RIP v1 to its limits because it is passing subnets in its routing advertisements but it is **not** including subnet masks. The router is applying it's own subnet mask to these subnets based on how its own matching interface is configured. There are no static routes required for convergence.

Scenario 3

Scenario 2 examines RIPv1 running on a stub network. SanJose1 and SanJose2 make up the “stub network” of the small XYZ Company as shown below. This company has an internet connection via their ISP which uses the Baypointe router. XYZ company uses the 172,30.00 classful network which is subnetted into 172.30.1.0 / 24, 172.30.2.0 / 24 and 172.30.3.0 / 24. The ISP has a static route to the 172.30.0.0 network on Baypointe. A default route to the ISP is put on the SanJose1 router. This default route gets propagated to SanJose2 using the default-information originate command.

4 – Troubleshooting/Reflection

I did scenarios 1 & 2 on NetLab. However it was not possible to complete scenario 3 on NetLab because the `default-information originate` command did not result in propagating the default route via RIP. So for Scenario 3 I used the older routers (Istanbul Pod) in the lab and it worked fine.

NetLab uses IOS v12.0 and I noticed the debug trace output differs slightly from the examples in the original lab. With v12.0 you can see the “build update entries” but you don’t see the actual entries that are being sent out each interface.

5 – Lab Questions

No unanswered questions in this lab.

6 – Example Commands

```
! Configuring RIP v1
conf t
  router rip
    ! add only directly connected classful network for RIP to advertise
    network 192.168.4.0
    network 172.30.0.0
    ! undo any mistakes
    no network 172.30.0.0

    !propogate default GW (worked on lab routers, not on NetLab)
    default-information originate

    !propogate default GW (works on NetLab & lab)
    redistribute static

    !suppress announcements to stub networks
    passive-interface e0

! tracing RIP updates
debug ip rip
undebug ip rip
undebug all

! Disabling RIP
conf t
  no router rip

! Suppressing IOS annoyances
```

```
line con 0
 login
 password cisco
 logging synchronous
 exec-timeout 0 0
 exit
```

CIS 82 LAB 6: IGRP

Rich Simms

March 28, 2006

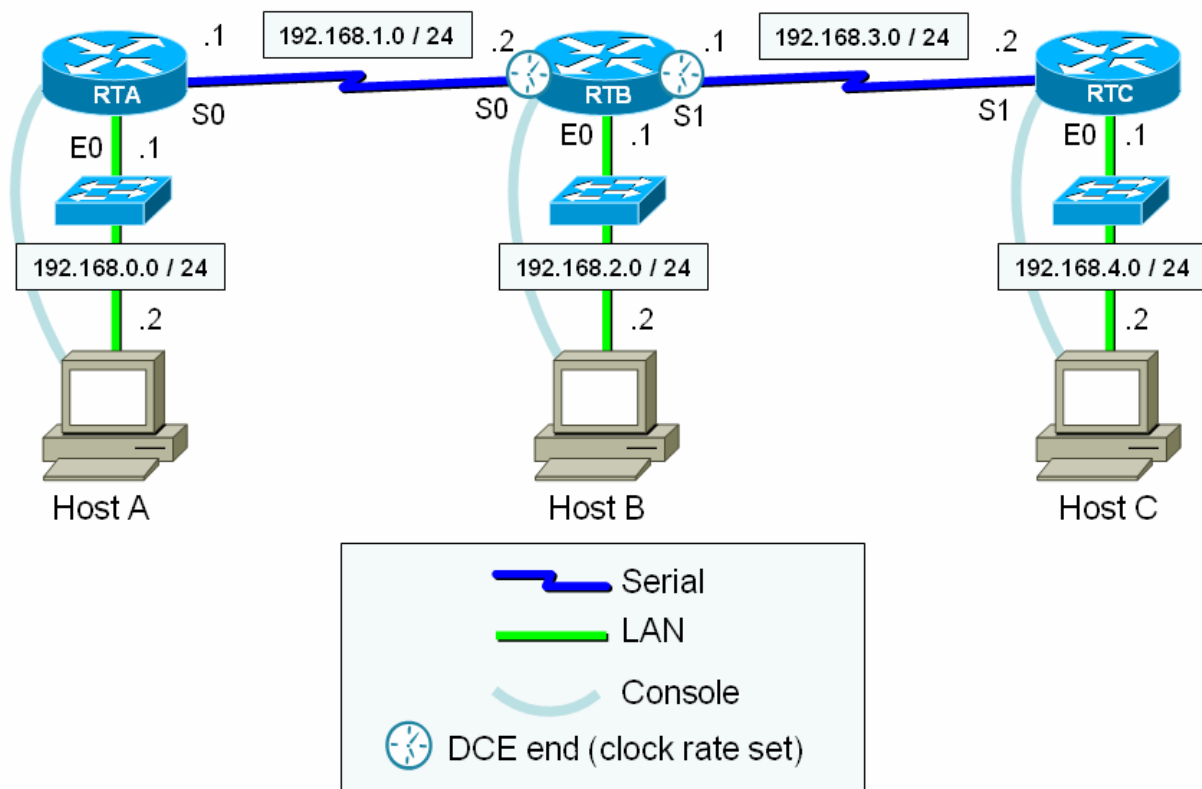

Teammates:

- Louis Arbanas
- Eric Jett
- Alf Popp

1 - Scenario

The objective for this lab is to learn how to configure IGRP. IGRP is classful like RIPv1. RIPv1's metric is based on number of hops. IGRP uses instead a composite metric based on bandwidth, delay, reliability, and load. The scenario below uses the standard three router setup we have been using in the other labs. All networks configured are classful.

2 - Diagram

RTB#undebg all
All possible debugging has been turned off

```

4 – Troubleshooting/Reflection

This lab took the least amount of time of all the labs. I built and tested the basic router configurations using PacketTracer then “pasted” the these configurations into the actual lab consoles. Once the basic configurations were completed I did the IGRP configuration manually.

I can see how IGRP would address RIP limitations in larger networks. The metrics used would result in better path selection and the limit of 15 hops gets extended to 255.

Gerlinde showed me how to use IOS help command (shown below) to determine the maximum number of hops for IGRP. The allowable range gets printed with the “?” after metric maximum-hops.

I also see now why we get “invalid source” routing updates. This is due to updates being broadcast by the routers out their Ethernet interfaces into a common switch. The broadcasts are flooded by the switch to all ports which are then picked up as inputs to the other routers Ethernet interfaces.

5 – Lab Questions

Use the command show ip protocols

```
RTB#show ip protocols
Routing Protocol is "igrp 364"
  Sending updates every 90 seconds, next due in 31 seconds
  Invalid after 270 seconds, hold down 280, flushed after 630
  Outgoing update filter list for all interfaces is
  Incoming update filter list for all interfaces is
  Default networks flagged in outgoing updates
  Default networks accepted from incoming updates
  IGRP metric weight K1=1, K2=0, K3=1, K4=0, K5=0
  IGRP maximum hopcount 100
  IGRP maximum metric variance 1
  Redistributing: igrp 364
  Routing for Networks:
    192.168.1.0
    192.168.2.0
    192.168.3.0
  Routing Information Sources:
    Gateway         Distance      Last Update
    192.168.1.1         100          00:00:04
    192.168.3.2         100          00:00:52
  Distance: (default is 100)
```

1. How often are IGRP updates being sent? 90 seconds
2. When is the next update due? 31 seconds
3. How long will it take for a route to become invalid? 270 seconds
4. How long will the route remain in hold down, or wait to accept a new route? 280 seconds
5. What is the value of the K-1 and the K-2 constants? K1=1, K2=0
6. What is the default maximum hop count? 100
7. What is the maximum hop count? 255

```
RTC(config-router)#metric maximum-hops ?
```

<1-255> Hop count

6 – Example Commands

```
!*****
! Configuring IGRP
!*****

config t
  router igrp 10
    network 192.15.25.0
    network 172.30.0.0

! Trace IGRP updates
debug ip igrp events
debug ip igrp transactions
! Changing bandwidth
conf t
  int s0
    bandwidth 128

! Configure IGRP timers for fast convergence
conf t
  router igrp 364
    timers basic 15 45 0 60
    no metric holddown
    metric maximum-hop 50
```

CIS 82 LAB 7: Access Control Lists

Rich Simms

May 2, 2006

Teammates:

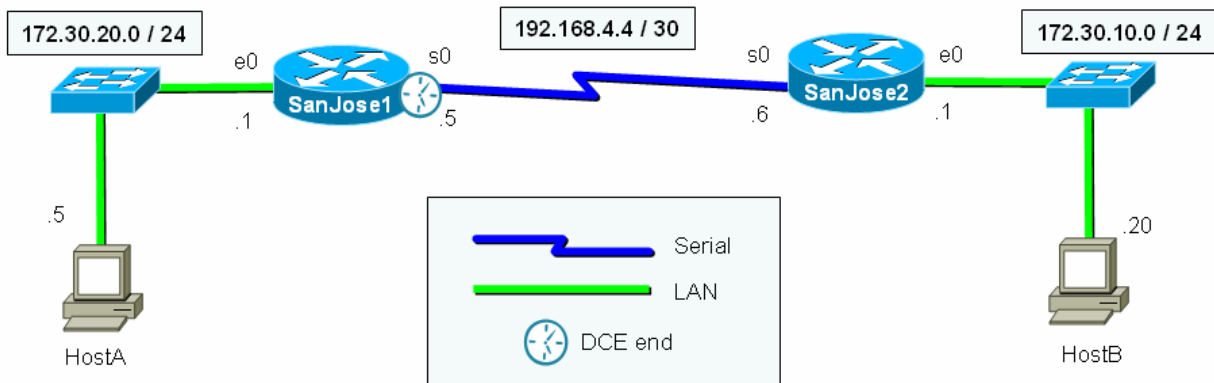

- Louis Arbanas
- Eric Jett
- Alf Popp

1 – Scenario

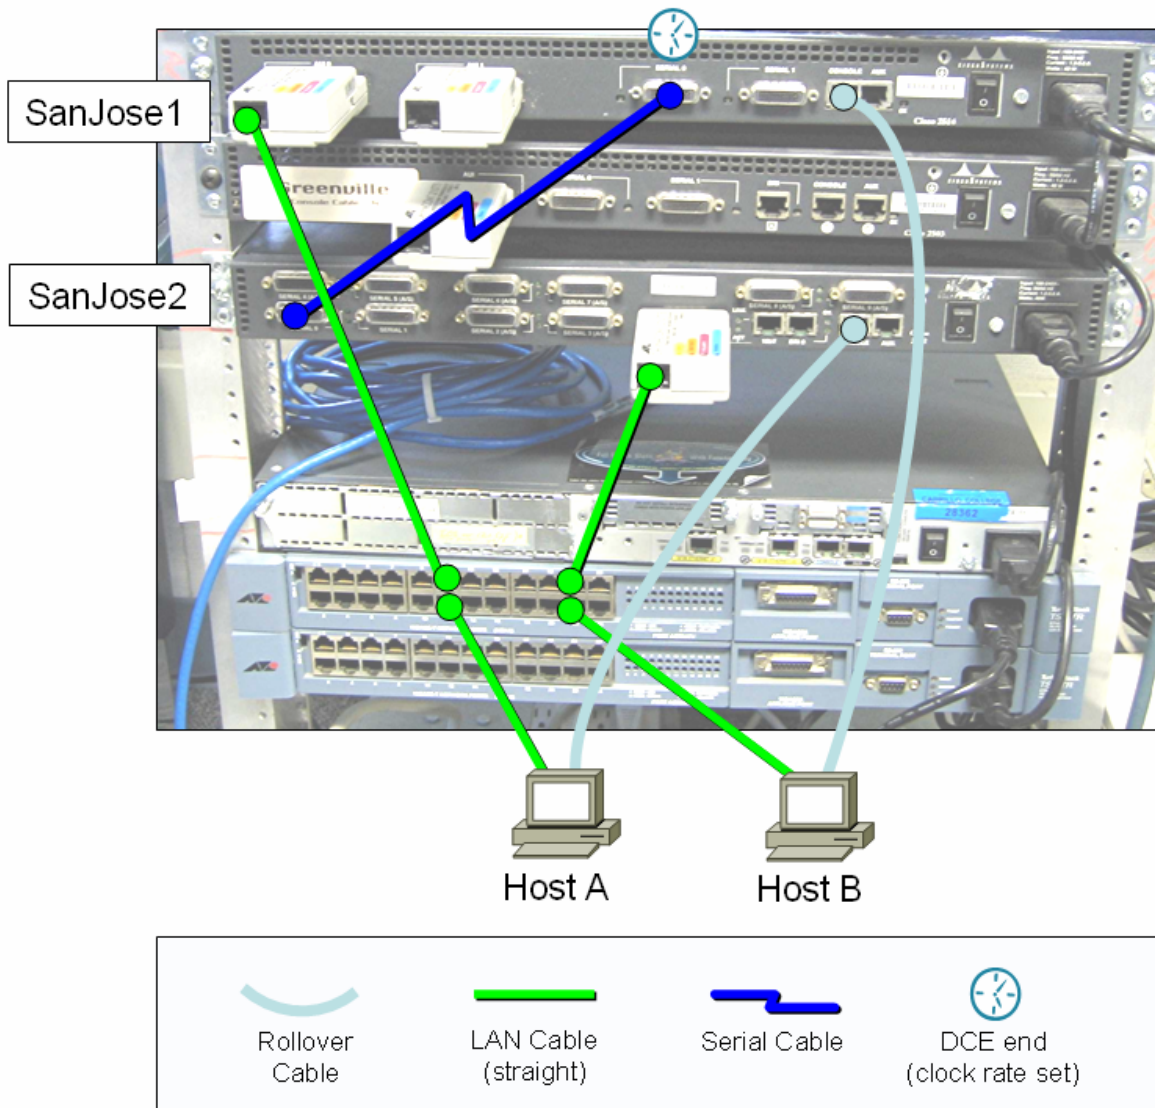

The objective of this lab was to learn how to implement access control lists. This lab utilizes two routers and two hosts as shown in the diagram below. The routers were connected by a serial link. A variety of access control lists are applied including standard, extended and named.

2 – Diagram

Logical view:

Physical view:

3 – Running Configurations

Task 1: Create a standard ACL that will deny all packets from HostB from reaching the 172.30.20.0/24 network.

	
<pre>SanJose1#show run Building configuration... Current configuration: ! version 12.0 service timestamps debug uptime service timestamps log uptime no service password-encryption ! hostname SanJose1 ! enable secret 5 \$1\$UcF\$ScmX8KHd5iSLgZWXM3iuH. ! ip subnet-zero no ip domain-lookup ip host SanJose1-s0 192.168.4.5 ip host SanJose1-e0 172.30.20.1 ip host HostA 172.30.20.5 ip host SanJose2-s0 192.168.4.6 ip host SanJose2-e0 172.30.10.1 ip host HostB 172.30.10.20 ! ! process-max-time 200 ! interface Ethernet0 description Connection to SanJose1 LAN ip address 172.30.20.1 255.255.255.0 no ip directed-broadcast ! < output omitted > ! interface Serial0 description Connection to SanJose2 ip address 192.168.4.5 255.255.255.252 ip access-group 1 in no ip directed-broadcast no ip mroute-cache no fair-queue clockrate 64000 ! interface Serial1 no ip address no ip directed-broadcast shutdown ! ! router rip version 2 network 172.30.0.0 network 192.168.4.0 no auto-summary ! ip classless ! access-list 1 deny 172.30.10.20 access-list 1 permit any</pre>	<pre>SanJose2#show run Building configuration... 4 – Troubleshooting/Reflection

This lab required a number of different configurations and reloads. Instead of typing in each command I created a complete set of commands for each task and router ahead of time and verified them on NetLab. Once I had the physical lab cabled and powered on I just copied and pasted into the TeraTerm console. I noticed TeraTerm is not fully compliant with standard Windows UI conventions. For example it used the right mouse key to do the paste operation and it lacks a “select all” under the Edit menu. In several previous labs I had mistakenly pasted the clipboard into the console by accident by clicking on the right mouse key.

The following tools were used to test ACL’s:

Ping from router:

Success	Fail
SanJose2#ping 172.30.20.1	SanJose2#ping 172.30.20.1
Type escape sequence to abort. Sending 5, 100-byte ICMP Echos to 172.30.20.1, timeout is 2 seconds: !!!! Success rate is 100 percent (5/5), round-trip min/avg/max = 32/32/32 ms SanJose2#	Type escape sequence to abort. Sending 5, 100-byte ICMP Echos to 172.30.20.1, timeout is 2 seconds: U.U.U Success rate is 0 percent (0/5) SanJose2#

Extended ping from router:

Success	Fail
SanJose2#ping Protocol [ip]: Target IP address: 172.30.20.1 Repeat count [5]: Datagram size [100]: Timeout in seconds [2]: Extended commands [n]: y Source address or interface: 172.30.10.1 Type of service [0]: Set DF bit in IP header? [no]: Validate reply data? [no]: Data pattern [0xABCD]: Loose, Strict, Record, Timestamp, Verbose[none]: Sweep range of sizes [n]:	SanJose2#ping Protocol [ip]: Target IP address: 172.30.20.5 Repeat count [5]: Datagram size [100]: Timeout in seconds [2]: Extended commands [n]: y Source address or interface: 172.30.10.1 Type of service [0]: Set DF bit in IP header? [no]: Validate reply data? [no]: Data pattern [0xABCD]: Loose, Strict, Record, Timestamp, Verbose[none]: Sweep range of sizes [n]:
Type escape sequence to abort. Sending 5, 100-byte ICMP Echos to 172.30.20.1, timeout is 2 seconds: !!!! 5 – Lab Questions

Regarding Task 6 ICMP packets captured on Ethereal when attempting to connect to 192.168.4.5

What is the type and code? Type 3, Code 13

6 – Example Commands

! Enable router's web UI
 Router#ip http server

```

! Standard access list example
interface Serial0
  ip access-group 1 in
!
access-list 1 deny 172.30.10.20
access-list 1 permit any

! Extended access list example
interface Serial0
  ip access-group 101 in
access-list 101 deny tcp host 172.30.10.20 host 192.168.4.5 eq telnet
access-list 101 permit ip any any

! Named access control list example
interface Serial0
  ip access-group Restrict-172.30.10.0/24-Access in
!
ip access-list extended Restrict-172.30.10.0/24-Access
deny icmp 172.30.10.0 0.0.0.255 any echo
permit tcp 172.30.10.0 0.0.0.255 host 172.30.20.1 eq telnet
deny tcp 172.30.10.0 0.0.0.255 any eq telnet
permit ip any any

SanJose1#show access-lists
Extended IP access list Restrict-172.30.10.0/24-Access
deny icmp 172.30.10.0 0.0.0.255 any echo (24 matches)
permit tcp 172.30.10.0 0.0.0.255 host 172.30.20.1 eq telnet (48 matches)

```

CIS 82 - Case Study

Rich Simms

May 12, 2006

Objective

The objective of this case study is to design and implement a multi-site network from scratch. There will be three sites and one connection to the Internet. Each site will have 50 to 80 hosts. The network will need to be secured using Access Control Lists.

Diagram

Logical view

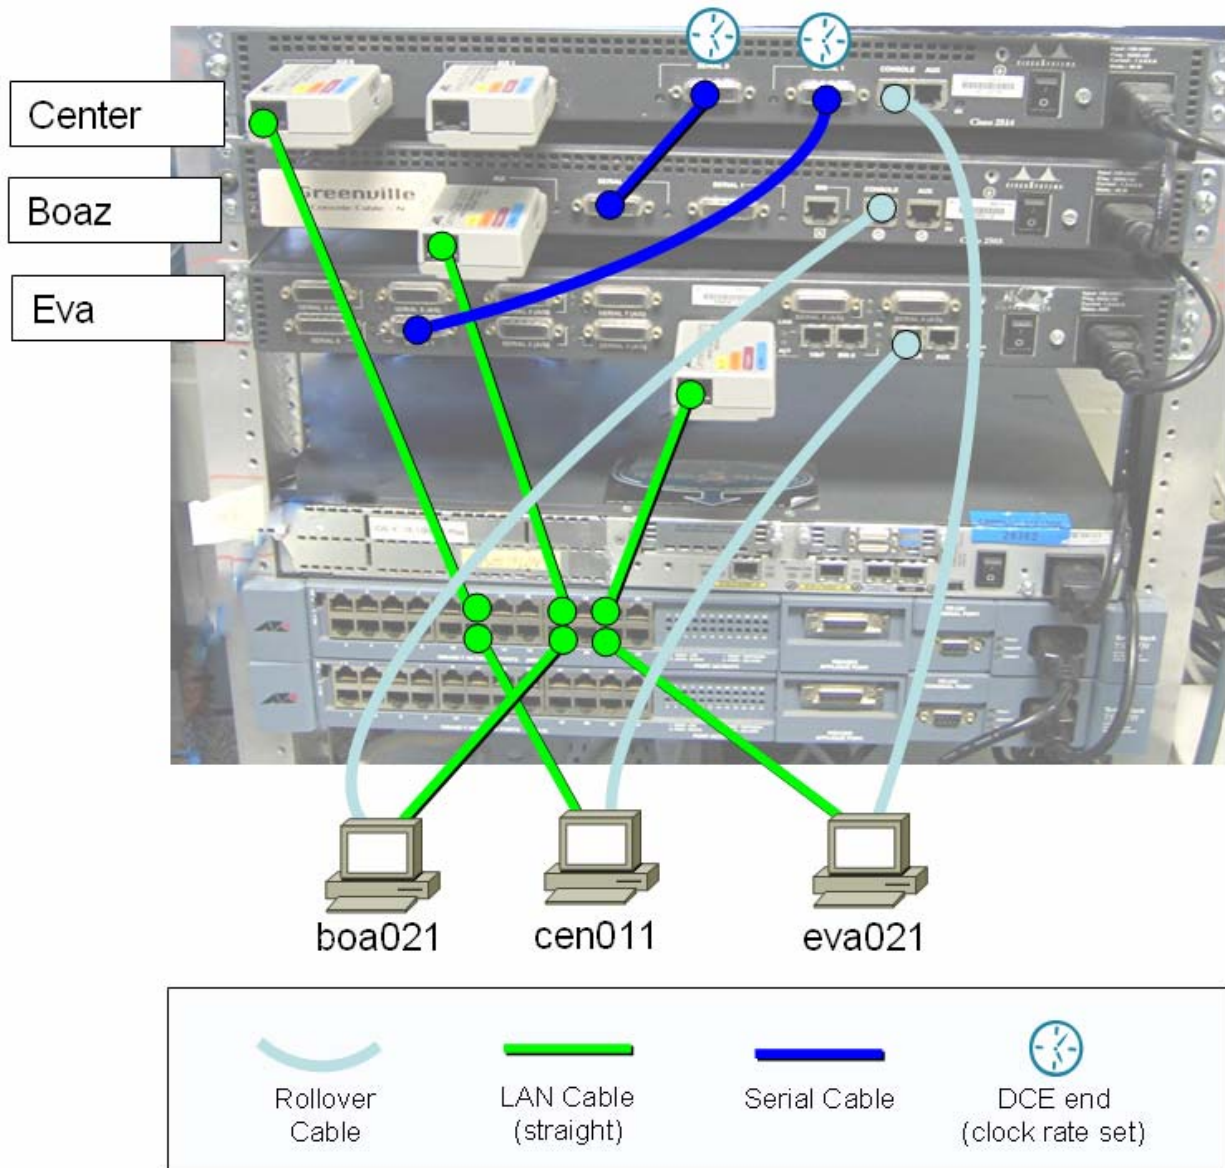

Classful networks and subnets (indented):

192.168.1.0
 192.168.1.0 / 30
 192.168.1.4 / 30
192.168.2.0
192.168.3.0
192.168.4.0
63.0.0.0
 63.249.104.0 / 24

Physical view

IP Addressing Scheme

We have three sites Boaz, Center, and Eva. We will be using the 192.168.0.0 private network and subnet it into multiple class C networks for each site. These networks will all have a /24 mask. In addition the 192.168.1.0 network will be further subnetted into multiple /30 subnets to use for serial links which only need two host addresses for each end of the serial connection.

Currently each site only has 50-80 hosts but with the Class C networks they have room for growth. Each class C network can have up to 254 hosts. The IP addressing scheme for the sites will be to have the ending .1 address always assigned to the router interface. The addresses ending in .2 to .20 will be reserved for non-clients (printers, servers, switches, etc.) The

remaining addresses up to the one ending with .254 will be used for client desktops and workstations. The hostnames for the routers will be the same as the site names. All other hostnames will be based on the first three letters of the site name plus the last portion of the IP address. For example boa022 will be the hostname for a client on the Boaz site which has an IP address of 192.168.2.22.

Subnet table

Subnet	Network address	Mask	Classful	Host range	Broadcast address	Usable	Status
0	192.168.0.0	/24	Yes (C)	192.168.0.1 to 192.168.0.254	192.168.0.255	yes	available
1	192.168.1.0	/24	Yes (C)	192.168.1.1 to 192.168.1.254	192.168.1.255	yes	Serial links
2	192.168.2.0	/24	Yes (C)	192.168.2.1 to 192.168.2.254	192.168.1.255	yes	Boaz LAN
3	192.168.3.0	/24	Yes (C)	192.168.3.1 to 192.168.3.254	192.168.1.255	yes	Center LAN
4	192.168.4.0	/24	Yes (C)	192.168.4.1 to 192.168.4.254	192.168.1.255	yes	Eva LAN
...	available
254	192.168.254.0	/24	Yes (C)	192.168.254.1 to 192.168.254.254	192.168.254.255	yes	available
255	192.168.255.0	/24	Yes (C)	192.168.255.1 to 192.168.255.254	192.168.255.255	no	unusable

In addition the 192.168.1.0 network above will be further subnetted for multiple serial links

Subnet	Network address	Mask	Classful	Host range	Broadcast address	Usable	Status
0	192.168.1.0	/30	No (CIDR)	192.168.0.1 to 192.168.0.2	192.168.0.3	yes	Boaz-Center WAN

192	168	...	0	/24	...	networks	192.168.6.0 to 192.168.254.0	available
192	168	255	0	/24	192.168.255.0000 0000	network	192.168.255.255	unusable

Routing Protocol and default gateway

The routers will be configured with the RIP v2 protocol to exchange routing table information. V2 is necessary since the serial link networks are not classful. A default gateway will be configured on Eva to the “Internet” (loopback interface). To propagate this route via RIP advertisements the `redistribute static` command is used.

Access Control Lists

The server cen011 (192.168.3.11) on the Center LAN is running a restricted access web server. Access to this server is restricted to Center and Eva LAN users. Eva LAN users are further restricted to port 80 (HTTP) access only on this server. No other users may access is server. Access control will be implemented as follows:

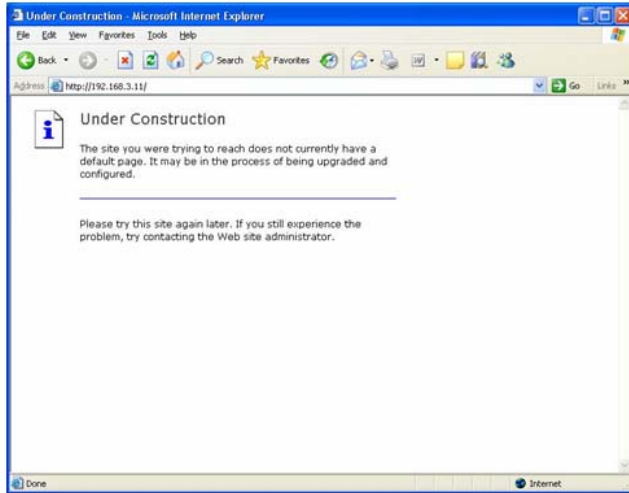

On Center:

```
access-list 101 permit tcp 192.168.4.0 0.0.0.255 host 192.168.3.11 eq 80
access-list 101 deny ip any host 192.168.3.11
access-list 101 permit ip any any
```

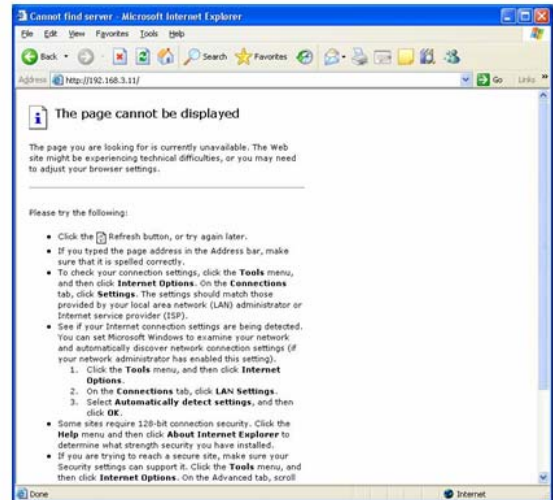

On Center’s e0 interface:

```
ip access-group 101 out
```

 <p>Center e0 (out)</p>	<pre>Extended IP access list 101 permit tcp 192.168.4.0 0.0.0.255 host 192.168.3.11 eq www (10 matches) deny ip any host 192.168.3.11 (62 matches) permit ip any any (275 matches)</pre>

s1	DTE	1544 Kbit	Serial link to Center	192.168.1.4 /30	192.168.1.6	255.255.255.252
loopback	na	na	Simulated Internet	63.249.104.0 /24	63.249.104.42	255.255.255.0

Convergence

To verify convergence all nodes were checked to be able to ping all other nodes successfully. This utilized the ping commands on both the routers and the Windows hosts. To make use of the loopback “internet” address as a source address the extended ping command was used.

With the ACL activated, access to the web server on Center LAN was only successful using a web browser from the Center or Eva LANs. All other source IP packets were dropped.

Troubleshooting/Reflection

I had a problem with the serial connection between Center and Eva. I used ping, show ip int brief, and show controllers to see the line was not up. I looked at my cables and saw the serial cable was not connected correctly.

I had setup and tested the route configurations previously on NetLab so that part went quite fast. I brought edited config files that I just “pasted” into TeraTerm consoles. This saved a lot of time.

Successful propagation of the default gateway varied across different routers. It was discovered that using the alternative default-information originate or the default-network x.x.x.x commands also worked on the older Sydney pod routers running v12.0. However the default-information originate command did not propagate the default route on the NetLab pod.

For the fake Internet address configured on Eva’s loopback interface I used the actual settings I found on my home network’s DSL connection to Cruzio. I don’t have a static IP with this ISP so that is probably why they use a /24 network rather than a /30 network.

CIS 82 Lab - SBA Practice – Paper Handout

Rich Simms

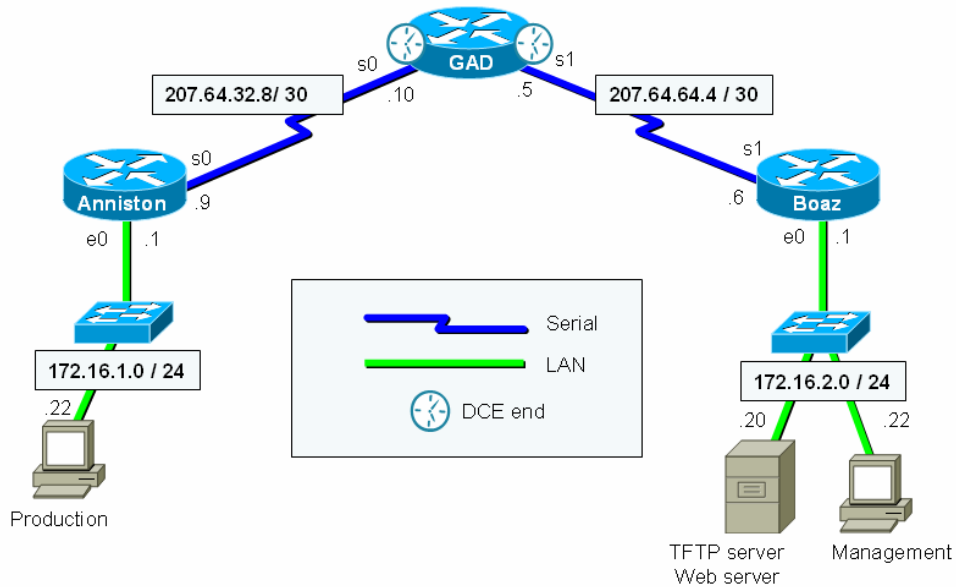

May 15, 2006

1 – Scenario

The objective of this exercise was to practice setting up three routers in anticipation of the skills based assessment. The objective was to take the practice SBA handout from class and implement it. The access control requirements are:

“... denies the production network PC access to the web server. Access to the tftp server needs to be allowed ... Deny all telnet access to the Boaz router. You should always be able to telnet and ping to the other routers in your network”

2 – Diagram

3 – Running Configurations

Anniston	Gad	Boaz
<pre>anniston#show run Building configuration... Current configuration : 1192 bytes ! version 12.2 service timestamps debug uptime service timestamps log uptime no service password-encryption ! hostname anniston ! enable secret 5</pre>	<pre>gad#show run Building configuration... Current configuration : 1177 bytes ! version 12.2 service timestamps debug uptime service timestamps log uptime no service password-encryption ! hostname gad ! enable secret 5</pre>	<pre>boaz#show run Building configuration... Current configuration : 1613 bytes ! version 12.2 service timestamps debug uptime service timestamps log uptime no service password-encryption ! hostname boaz ! enable secret 5</pre>

3) *Transport command:*

```
line vty 0 4
transport input none
```

This will also result in connection refused commands. "transport" is generally used to allocate different vty ranges to different protocols (ie, on a protocol translator.)

4) *autocommand:*

```
line vty 0 4
autocommand quit
```

In this case the connection is accepted, but as soon as the resulting exec is ready to execute a command, it will execute the "quit" autocommand instead, which immediately closes the connection again. This has the advantage (?) that any banner that is configured will be displayed before disconnecting the user. So if you want to write nasty messages about unauthorized access and so on, you get a chance..

4- Troubleshooting / Reflection

I implemented these configurations on NetLab so could not fully test the ACL's.

Example IOS commands

- Develop IP address plan
- Draw map – label interfaces, DCE, IP networks, IP addresses, host names
- Notepad ACL's

Global Config

- clock set (optional) [clock set 18:00:00 9 Feb 2006]
- router hostname hostname boaz
- privilege mode PW enable secret class
- no dns timeouts no ip domain-lookup
- banner banner motd #
- ip hosts ip host boaz-e0 192.168.1.1
- ip host internet 207.64.4.5
- ip host web-server 192.168.3.20

Lines

- console line con 0
 - login
 - password cisco
 - logging synchronous
 - exec-timeout 0 0
- aux line aux 0
 - login
 - password cisco
- vty line vty 0 4
 - login
 - password cisco

Interfaces

- int (s, l, e, f)
- ip ip add 192.168.2.1 255.255.255.0
- description description Connection to Boaz LAN
- clock rate clock rate 64000
- enable no shut
- Static routes** ip route 172.16.1.0 255.255.255.0 192.168.1.2
- Default gateway** ip route 0.0.0.0 0.0.0.0 192.168.1.2
- ip route 0.0.0.0 0.0.0.0 10
- Routing protocols** router rip
 - version 2
 - no auto-summary
 - network 192.168.2.0
 - network 192.168.3.0
 - redistribute static (*only on router with static default GW*)
- convergence** ping, extended ping
- ACLs (use notepad)**

Class A: 0-127 (255.0.0.0)	/25	255.255.255.128	0.0.0.127	1000	0000
Class B: 128-191 (255.255.0.0)	/26	255.255.255.192	0.0.0.63	1100	0000
Class C: 192-223 (255.255.255.0)	/27	255.255.255.224	0.0.0.31	1110	0000
Class D: 224-239	/28	255.255.255.240	0.0.0.15	1111	0000
	/29	255.255.255.248	0.0.0.7	1111	1000
	/30	255.255.255.252	0.0.0.3	1111	1100

1-99 standard IP
100-199 extended IP

More TCP: www = 80

host n.n.n.n = n.n.n.n 0.0.0.0

```
!verify ACL's
show access-lists
show running-config
show ip int s0
```

Anatomy Of An Access List

List No.	Rule	Pattern Definition						
access-list xxx (100-199)	permit or deny	IP or ICMP	Source IP address xxx.xxx.xxx.xxx	Source IP address mask xxx.xxx.xxx.xxx 255=ignore 0=apply	Destination IP address xxx.xxx.xxx.xxx	Destination IP address mask xxx.xxx.xxx.xxx 255=ignore 0=apply	eq=equal gt=greater than lt=less than neq=not equal	TCP or UDP destination port no.
1	2	3	4	5	6	7	8	9

 Required
 Optional

- Every extended access list has a number from 100 to 199, which identifies the list in two places. When building the list, every line must be labeled with the same access list number. When you apply the list to an interface on the router, you must reference it by the same number. Version 11.2 of the IOS allows you to use a name for the list instead of a number.
- A permit or deny rule has to be applied to every line or statement on the list.
- If you are only filtering on IP address, you will specify IP (or ICMP for pings and trace routes) as the protocol. This means that only the IP address is considered for a match. If you are also filtering on UDP or TCP port, you must specify TCP or UDP.
- Every line in the list must have a source address.
- Every IP source address in the list must have a mask. The mask lets you determine how much of the preceding IP address to apply to the filter. In most cases, you will simply want to put a 255 corresponding to every octet in the IP address that you want to ignore, and 0 for every octet that you want the packet match to apply to.
- Every line in the list must have a destination address.
- Every IP destination address in the list must have a mask. See 5 above.
- This applies to the TCP or UDP port that you are filtering on. In most cases, you will use the eq, which means equals. This gives you the ability to permit or deny TCP or UDP ports equal to the port specified. There are cases, however, where you will want to apply a range of port numbers, which is where the gt, greater than, or lt, less than, will come in handy.
- If you have defined the pattern as a TCP or UDP packet, you will have to have an associated port number.

Anatomy Of An Access List

List No.	Rule	Pattern Definition						
access-list xxx (100-199)	permit or deny	IP or ICMP TCP or UDP	Source IP address xxx.xxx.xxx.xxx	Source IP address mask xxx.xxx.xxx.xxx 255=ignore 0=apply	Destination IP address xxx.xxx.xxx.xxx	Destination IP address mask xxx.xxx.xxx.xxx 255=ignore 0=apply	eq=equal gt=greater than lt=less than neq=not equal	TCP or UDP destination port no.
1	2	3	4	5	6	7	8	9
1) Every extended access list has a number from 100 to 199, which identifies the list in two places. When building the list, every line must be labeled with the same access list number. When you apply the list to an interface on the router, you must reference it by the same number. Version 11.2 of the IOS allows you to use a name for the list instead of a number. 2) A permit or deny rule has to be applied to every line or statement on the list. 3) If you are only filtering on IP address, you will specify IP (or ICMP for pings and trace routes) as the protocol. This means that only the IP address is considered for a match. If you are also filtering on UDP or TCP port, you must specify TCP or UDP. 4) Every line in the list must have a source address.					5) Every IP source address in the list must have a mask. The mask lets you determine how much of the preceding IP address to apply to the filter. In most cases, you will simply want to put a 255 corresponding to every octet in the IP address that you want to ignore, and 0 for every octet that you want the packet match to apply to. 6) Every line in the list must have a destination address. 7) Every IP destination address in the list must have a mask. See 5 above. 8) This applies to the TCP or UDP port that you are filtering on. In most cases, you will use the eq, which means equals. This gives you the ability to permit or deny TCP or UDP ports equal to the port specified. There are cases, however, where you will want to apply a range of port numbers, which is where the gt, greater than, or lt, less than, will come in handy. 9) If you have defined the pattern as a TCP or UDP packet, you will have to have an associated port number.			
Required		Optional						

From: p118 Network Computing - April 15, 1998 - www.networkcomputing.com

```

config t
  access-list 101 permit tcp 192.168.4.0 0.0.0.255 host 192.168.3.11 eq 80
  access-list 101 deny ip any host 192.168.3.11
  access-list 101 permit ip any any

int e0
  
```

```

    ip access-group 101 out

!removing ACL's
no access-list 101
int e0
    no ip access-list 101 out

!Named ACL example
config t
    ip access-list extended server-access
        permit TCP any host 131.108.101.99 eq smtp
        permit UDP any host 131.108.1.1.99
        deny ip any any log
    ^z

    int fa 0/0
    ip access-group server-access out
    ^z

!advanced ACL's
access-list 102 permit tcp any any established
access-list 102 permit icmp any any echo-reply
access-list 102 permit icmp any any unreachable

!verify ACL's
show access-lists
show running-config
show ip int s0

!Disable telnet access to a router (from BillW@Cisco)
1) require an impossible login:
    line vty 0 4
    login
    no password

2) Line access lists:
    access-list 77 deny 0.0.0.0 0.0.0.0
    ! (implied deny everything else)
    line vty 0 4
    access-class 77 in

3) Transport command:
    line vty 0 4
    transport input none

4) autocommand:
    line vty 0 4
    autocommand quit
